## DIAGNOSTIC METHOD AND APPARATUS FOR NON-DESTRUCTIVELY OBSERVING LATCH DATA

### Background of Invention

[0001]           Field of the Invention

[0002]           The present invention generally relates to latch circuits and more particularly to a circuit that examines the data within the latch circuit without altering or destroying the data.

[0003]           Description of the Related Art

[0004]           When bringing up and debugging logic state machines, it is of interest to be able to observe the state of latches for parts or all of the logic on the device without destroying the state of those latches. This is important both for initialization and for debug of follow-on manufacturing processes. It is also an advantage for the method of observation not to require prior knowledge of the latch constitution.

data is returned to the same position within the shift register before and after the circular transfer of the data.

[0008]        The invention uses the foregoing circuit to provide a method for observing data within a shift register without altering the data. The method selects a shift register from many shift registers and then continually transfers data from the output of the shift register to the input of the shift register and back through the shift register in a circular manner. The method outputs data as the data is transferred from the output of the shift register to the input of the shift register to permit data within the shift register to be observed outside the circuit without altering the data within the shift register. This allows the invention to send data to a location external to the shift register to allow the shift register to be examined by an external device.

[0009]        The process of selecting the shift register comprises controlling selectors to form a circuit between the output of the shift register and the input of the shift register by connecting a wiring loop between the output of the shift register and the input of the shift register. This method can optionally store the data in a memory location separate from the shift register. As mentioned above, the invention provides the ability to alter the data between the time the data is received from the output of the shift register and the data is transferred to the input of the shift register.

[0010]        The circular data transfer is performed for a single data transfer loop such that the data is at the same position within the shift register before and after the data transfer process. This method can determine the length of the shift register by sending a unique data marker circularly through the shift register and counting the number of bits that pass through the shift register as the unique marker completes the circular loop through the shift register before circularly transferring the data.

## Brief Description of Drawings

# Summary of Invention

[0005]           The invention provides a circuit that can observe data within shift registers without altering the data. The circuit includes selectors connected to the inputs and outputs of the shift registers. The selectors selectively connect the input with the output of a selected shift register to form a wiring loop for the selected shift register. A control device connected to the wiring loop uses the wiring loop to cause the data to be continually transferred from the output of the selected shift register to the input of the selected shift register and back through the selected shift register in a circular manner. The control device includes a data output accessible from outside the circuit. An observation wire is connected to the wiring loop, and the data passes from the wiring loop to the control device through the observation wire. The control device outputs data appearing on the wiring loop as the data is circulated through the selected shift register to permit data within the selected shift register to be observed outside the circuit without altering the data within the selected shift register.

[0006]           The inventive control device has a shift register selector connected to the selectors that cause the selectors to form the wiring loop using one or more different shift registers from the selected shift register. The control device can optionally include a storage device for recording the data as the data appears on the wiring loop. The invention can also include a write device for changing one or more bits of data within the shift register before the data is returned to the input of the shift register.

[0007]           The control device can maintain data on the different lengths of the different shift registers or the control device can include a shift register length determination unit that sends a unique data marker circularly through the shift register and counts the number of bits that pass through the wiring loop as the unique marker completes the circular loop through the shift register and returns to the wiring loop. A shift register length control unit limits the circular transfer of data within the wiring loop and the shift register such that all of the data is circulated through the wiring loop a single time and the

[0011] The foregoing invention will be better understood from the following detailed description with reference to the drawings, in which:

[0012] Figure 1 is a schematic diagram of one embodiment of the inventive circuit;

[0013] Figure 2 is a flow diagram illustrating a preferred method of the invention;  
and

[0014] Figure 3 is a hardware embodiment for use with the invention.

## Detailed Description

[0015] As mentioned above, it is of interest to be able to observe the state of latches for parts or all of the logic on the device without destroying the state of those latches. It is also an advantage for this observation not to require prior knowledge of the length of the shift register. The invention described below provides a circuit and method for the circular shifting of varying length rotating shift registers and observation (or control) of each bit in the shift register during a circular shift process. The process ultimately restores the data back to the original positions in the latches of the shift register. In order to limit the need to have knowledge of any particular design, this invention also contains logic that can be used in a separate pre-operated mechanism to determine the length of each shift register that needs to be observed. This allows the method to work independently of any particular chip design.

[0016] As shown in Figure 1, the invention provides a circuit that can observe data within shift registers without altering the data. The circuit includes selectors (e.g., multiplexors) 106, 107 connected to the inputs 121 and outputs 122 of the shift registers 112-114. The selectors 106, 107 selectively connect the input with the output 122 of one of the shift registers 112-114 to form a wiring loop 105 for the selected shift register.

[0017] A control device 100 connected to the wiring loop 105 uses the wiring loop 105 to cause the data to be continually transferred from the output 122 of the selected shift register to the input 121 of the selected shift register and back through the selected shift register in a circular manner. The control device 100 includes a data input/output 103 that is accessible from outside the circuit. The data input/output 103 is also used to input the different lengths of the shift registers 112-114, if these lengths are known. Item 102 represents the external control input for the control device logic 100.

[0018] In an alternative embodiment, described below, the invention can determine the length of each shift register. At the beginning of the shift register length determination operation the selected shift register of interest 112, 113 or 114 is initialized to contain all logical "0"s. A logical "1" is then provided by the control device 100 as a length marker into the selected shift register 112, 113 or 114 along signal line 116 to a multiplexor 110. The signal 115 from the control device 100 is used to select the logical "1" to be loaded into the selected shift register during the shift register length determination operation. The control device 100 can observe (via signal path 118) the contents of the selected shift register 112, 113 or 114 as the shift operation is performed and a counter 130 within the control device 100 will count shift cycles until the logical "1" is observed. The counter 130 now contains the length of the selected shift register 112, 113 or 114 and this length can be stored in one of multiple length storage registers 132, 133 or 134 within the control device 100 for future use when rotating data in one of the selected shift registers 112, 113 or 114. Length storage register 132 will store the length of shift register 112, and length storage register 133 will store the length of shift register 113 and so on and so forth, each shift register length being stored into a dedicated length storage register 132-134 within the control device 100. Signal line 115 is connected to the multiplexor 110 and allows the control device 100 to determine when all the data within the shift registers 112-114 has been circularly transferred through the wiring loop 105 and back into the shift registers 112-114. Thus, the length storage registers 132-134 within the control device 100 limits the circular transfer of data within the wiring loop 105 and the selected shift registers 112-114 such that all of the data is

circulated through the wiring loop 105 a single time and the data is at the same position within the selected shift register 112-114 before and after the circular transfer of the data.

[0019] Therefore, with the invention, after the data is circularly transferred through the wiring loop 105, it returns to its original position within each of the shift registers 112-114. Therefore, with the invention, the data within the shift registers 112-114 is left essentially undisturbed even after it has been fully observed. As described in an alternative embodiment discussed below, the invention can alter one or more of the bits of data within the shift registers 112-114 (as desired) as the data is being circularly transferred through the wiring loop 105.

[0020] An observation wire 118 is connected to the wiring loop 105, and the data passes from the wiring loop 105 to the control device 100 through the observation wire 118. The control device 100 outputs data appearing on the wiring loop 105 through the observation input/output port 103 as the data is circulated through the selected shift register and wiring loop 105 to permit data within the selected shift register to be observed outside the circuit without altering the data within the selected shift register.

[0021] The inventive control device 100 has a shift register selector portion 125 that is connected to the selectors 106, 107 through the selection line 117 that causes the selectors 106, 107 to form the wiring loop 105 using one of the shift registers 112-114. The control device 100 can optionally include a storage device 120 for recording the data as the data appears on the wiring loop 105. The data within the storage device can be observed through the input/output port 103. The internal connections, buses, etc., within the control device 100 are not illustrated so as not to obscure the salient features of the invention; however, such wiring connection would be well-known by those ordinarily skilled in the art.

[0022] The invention can also include a write device 127 for changing one or more bits of data within the shift register before the data is returned to the input 121 of the shift register. The write device 127 can output a new data bit along line 116 at the appropriate time to replace a pre-existing data bit within any individual latch (U1-U15) within the

various shift registers 112-114. Therefore, the multiplexor 110 selects the data appearing along line 116 in place of the data flowing from the shift register output 122 to replace a bit of data being written back into the input 121 of the shift register. More specifically, the control device logic 100 can be set such that operation of the control data 102, and observe length control pin 115 would result in modification of the particular bit then being shifted to the circular path 105. This allows modification of internal data without disturbing other bits in the chain. The control logic can be controlled either via scanning, shifting, or by direct primary input (PI) control. Therefore, for example, if the shift registers 112-114 maintained fuse data information, such information can be selectively changed using the invention.

[0023]           The control device 100 can maintain data on the different lengths of the different shift registers (as input through the input/output port 103) in the memory 120 or a separate memory. Alternatively, the control device 100 can include a shift register length determination unit 129 that sends a unique data marker circularly through the shift register and counts the number of bits that pass through the wiring loop 105 as the unique marker completes the circular loop through the shift register and returns to the wiring loop 105. Therefore, the invention can circulate a data bit comprising "1" along with a string of "0" data bits and count the number of bits that occur from the time the "1" data bit enters the input 121 of one of the shift registers 112-114 until the "1" returns back to the wiring loop 105 from the output 122 of the shift register. The invention preferably determines the lengths of the different shift registers 112-114 during an initialization process and records this information for later use. If desired, the invention can only determine the lengths of the shift registers that will be observed, or can determine the lengths of all shift registers.

[0024]           As shown in flowchart form in Figure 2, the invention uses the foregoing circuit to provide a method for observing data within a shift register without altering the data. The method selects a shift register 200 from many shift registers and then continually circularly transfers data 202 from the output 122 of the shift register to the input 121 of the shift register and back through the shift register in a circular manner.

The method outputs data 204 as the data is transferred from the output 122 of the shift register to the input 121 of the shift register to permit data within the shift register to be observed outside the circuit without altering the data within the shift register. This allows the invention to send data to a location external to the shift register to allow the shift register to be examined by an external device.

[0025] The process of selecting the shift register 200 comprises controlling selectors 106, 107 to form a circuit between the output 122 of the shift register and the input 121 of the shift register by connecting a wiring loop 105 between the output 122 of the shift register and the input 121 of the shift register. This method can optionally store the data in a memory location separate from the shift register 206. As mentioned above, the invention provides the ability to alter the data between the time the data is received from the output 122 of the shift register and when the data is transferred to the input 121 of the shift register.

[0026] The circular data transfer 202 is performed for a single data transfer loop such that the data is at the same position within the shift register before and after the data transfer process. This method can determine the length of the shift register by sending a unique data marker (as discussed above) circularly through the shift register and counting the number of bits that pass through the shift register as the unique marker completes the circular loop through the shift register.

[0027] A representative hardware environment for practicing the present invention is depicted in Figure 3, which illustrates a typical hardware configuration of an information handling/computer system in accordance with the subject invention, having at least one processor or central processing unit (CPU) 10. CPUs 10 are interconnected via system bus 12 to random access memory (RAM) 14, read-only memory (ROM) 16, an input/output (I/O) adapter 18 for connecting peripheral devices, such as disk units 11 and tape drives 13, to bus 12, user interface adapter 19 for connecting keyboard 15, mouse 17, speaker 303, microphone 304, and/or other user interface devices such as touch screen device (not shown) to bus 12, communication adapter 305 for connecting the information handling system to a data processing network, and display adapter 301 for

connecting bus 12 to display device 302. A program storage device readable by the disk or tape units is used to load the instructions which operate the invention also loaded onto the computer system.

[0028]           The control logic 100, either as part of a normal operation, or as a specific operation code can be programmed to select one of the shift registers 112-114, and cause that shift register to shift in a rotating circular fashion via the two multiplexors 106, 107. This allows the data in that shift register to be observed out of the observation input/output 103. Upon completion of the rotating shift operation, the initial value of the shift register is restored. Because this is a shift in a circular fashion, the control logic 100 only needs to shift the number of elements in the shift register in order to restore the data back to its original position.

[0029]           The invention avoids using the standard LSSD scan clocks which destroy data in the rest of the latches on the chip, including latches within the circuit of interest, and restores data to the original position in latches.

[0030]           While the invention has been described in terms of preferred embodiments, those skilled in the art will recognize that the invention can be practiced with modification within the spirit and scope of the appended claims.

Claims {e1}

1. A circuit for observing data within a shift register without altering said data, said circuit comprising:

a wiring loop connecting the input of said shift register with the output of said shift register; and

a control device connected to said wiring loop, wherein said control device is adapted to use said wiring loop to cause said data to be continually transferred from said output of said shift register to said input of said shift register and through said shift register in a circular manner, and

wherein said control device includes a data output accessible from outside said circuit and wherein said control device outputs data appearing on said wiring loop as said data is circulated through said shift register to permit said data within said shift register to be observed outside said circuit without altering said data within said shift register.

{e2}

2. The circuit in claim 1, wherein said control device includes a shift register length control unit adapted to limit the circular transfer of data within said wiring loop and said shift register such that all of said data is circulated through said wiring loop a single time, and such that said data is at the same position within said shift register before and after said circular transfer of said data.

{e3}

3. The circuit in claim 1, wherein said control device includes a storage device adapted to record said data as said data appears on said wiring loop.

{e4}

4. The circuit in claim 1, wherein said control device includes a write device adapted to change one or more bits of data within said shift register.

{e5}

5. The circuit in claim 1, wherein said control device includes a shift register length determination unit adapted to send a unique data marker circularly through said shift register and count the number of bits that pass through said wiring loop as said unique marker completes the circular loop through said shift register and returns to said wiring loop and which also includes at least one register adapted to store said result from said counter as a determined shift register length.

{e6}

6. The circuit in claim 1, further comprising an observation wire connected to said wiring loop, wherein said data passes from said wiring loop to said control device through said observation wire.

{e7}

7. A circuit for observing data within a plurality of shift registers without altering said data, said circuit comprising:

a plurality of selectors connected to the inputs and outputs of said shift registers, wherein said selectors selectively connect the input of a selected shift registers with the output of said selected shift register to form a wiring loop for said selected shift register; and

a control device connected to said wiring loop, wherein said control device is adapted to use said wiring loop to cause said data to be continually transferred from said output of said selected shift register to said input of said selected shift register and through said selected shift register in a circular manner, and

wherein said control device includes a data output accessible from outside said circuit and wherein said control device outputs data appearing on said wiring loop as said data is circulated through said selected shift register to permit said data within said selected shift register to be observed outside said circuit without altering said data within said selected shift register.

{e8}

8. The circuit in claim 7, wherein said control device further comprises a shift register selector connected to said selectors, wherein said shift register selector is adapted to cause said selectors to form said wiring loop using one or more different shift registers from said selected shift register.

{e9}

9. The circuit in claim 7, wherein said control device maintains data on different lengths of said shift registers.

{e10}

10. The circuit in claim 7, wherein said control device includes a shift register length control unit adapted to limit the circular transfer of data within said wiring loop and said shift register such that all of said data is circulated through said wiring loop a single time, and such that said data is at the same position within said shift register before and after said circular transfer of said data.

{e11}

11. The circuit in claim 7, wherein said control device includes a storage device adapted to record said data as said data appears on said wiring loop.

{e12}

12. The circuit in claim 7, wherein said control device includes a write device adapted to change one or more bits of data within said shift register.

{e13}

13. The circuit in claim 7, wherein said control device includes a shift register length determination unit adapted to send a unique data marker circularly through said shift register and count the number of bits that pass through said wiring loop as said unique marker completes the circular loop through said shift register and returns to said wiring loop and which also includes at least one register adapted to store said result from said counter as a determined shift register length.

{e14}

14. The circuit in claim 7, further comprising an observation wire connected to said wiring loop, wherein said data passes from said wiring loop to said control device through said observation wire.

{e15}

15. A method for observing data within a shift register without altering said data, said method comprising:

continually transferring data from the output of said shift register to the input of said shift register and back through said shift register in a circular manner, and

outputting said data as said data is transferred from said output of said shift register to said input of said shift register to permit said data within said shift register to be observed outside said circuit without altering said data within said shift register.

{e16}

16. The method in claim 15, wherein said process of continually transferring said data is performed for a single data transfer loop such that said data is at the same position within said shift register before and after said process of continually transferring said data.

{e17}

17. The method in claim 15, wherein said outputting process further comprises storing said data in a memory location separate from said shift register.

{e18}

18. The method in claim 15, wherein said continually transferring process further comprises altering said data between the time said data is received from said output of said shift register and said data is transferred to said input of said shift register.

{e19}

19. The method in claim 15, further comprising, before said process of continually transferring said data, determining the length of said shift register by sending a unique data marker circularly through said shift register and counting the number of bits that pass through said shift register as said unique marker completes the circular loop through said shift register and returns to said wiring loop and further comprising storing said result from said counter as a determined shift register length.

{e20}

20. The method in claim 15, wherein said outputting process directs said data to a location external to said shift register to allow said shift register to be examined by an external device.

{e21}

21. A method for observing data within a shift register without altering said data, said method comprising:  
selecting said shift register from a plurality of shift registers;  
continually transferring data from the output of said shift register to the input of said shift register and back through said shift register in a circular manner, and  
outputting said data as said data is transferred from said output of said shift register to said input of said shift register to permit said data within said shift register to be observed outside said circuit without altering said data within said shift register.

{e22}

22. The method in claim 21, wherein said process of selecting said shift register comprises controlling selectors to form a circuit between said output of said shift register and said input of said shift register by connecting a wiring loop between said output of said shift register and said input of said shift register.

{e23}

23. The method in claim 21, wherein said process of continually transferring said data is performed for a single data transfer loop such that said data is at the same position within said shift register before and after said process of continually transferring said data.

{e24}

24. The method in claim 21, wherein said outputting process further comprises storing said data in a memory location separate from said shift register.

{e25}

25. The method in claim 21, wherein said continually transferring process further comprises altering said data between the time said data is received from said output of said shift register and said data is transferred to said input of said shift register.

{e26}

26. The method in claim 21, further comprising, before said process of continually transferring said data, determining the length of said shift register by sending a unique data marker circularly through said shift register and counting the number of bits that pass through said shift register as said unique marker completes the circular loop through said shift register and returns to said wiring loop and which also includes at least one register for storing said result from said counter as a determined shift register length.

{e27}

27. The method in claim 21, wherein said outputting process directs said data to a location external to said shift register to allow said shift register to be examined by an external device.

{e28}

28. A program storage device readable by machine, tangibly embodying a program of instructions executable by the machine to perform a method of observing data within a shift register without altering said data, said method comprising:

continually transferring data from the output of said shift register to the input of said shift register and back through said shift register in a circular manner, and

outputting said data as said data is transferred from said output of said shift register to said input of said shift register to permit said data within said shift register to be observed outside said circuit without altering said data within said shift register.

{e29}

29. The program storage device in claim 28, wherein said process of continually transferring said data is performed for a single data transfer loop such that said data is at the same position within said shift register before and after said process of continually transferring said data.

{e30}

30. The program storage device in claim 28, wherein said outputting process further comprises storing said data in a memory location separate from said shift register.

{e31}

31. The program storage device in claim 28, wherein said continually transferring process further comprises altering said data between the time said data is received from said output of said shift register and said data is transferred to said input of said shift register.

{e32}

32. The program storage device in claim 28, wherein said method further comprises, before said process of continually transferring said data, determining the length of said shift register by sending a unique data marker circularly through said shift register and counting the number of bits that pass through said shift register as said unique marker completes the circular loop through said shift register and returns to said wiring loop and further comprises storing said result from said counter as a determined shift register length.

{e33}

33. The program storage device in claim 28, wherein said outputting process directs said data to a location external to said shift register to allow said shift register to be examined by an external device.

## Abstract of Disclosure

The invention provides a circuit that can observe data within shift registers without altering the data. The circuit includes selectors connected to the inputs and outputs of the shift registers. The selectors selectively connect the input with the output of a selected shift register to form a wiring loop for the selected shift register. A control device connected to the wiring loop uses the wiring loop to cause the data to be continually transferred from the output of the selected shift register to the input of the selected shift register and back through the selected shift register in a circular manner. The control device includes a counter used for determining the length of a selected shift register and a set of registers to store, for future use when rotating data in the shift registers, the length of each shift register. The control device also includes a data output accessible from outside the circuit. An observation wire is connected to the wiring loop, and the data passes from the wiring loop to the control device through the observation wire. The control device outputs data appearing on the wiring loop as the data is circulated through the selected shift register to permit data within the selected shift register to be observed outside the circuit without altering the data within the selected shift register.
